# A Model of Single Value of Property for Multipurposes (SVMP) Based on Government's Tax Value Approach – Case of Antapani Kidul Housing District, Municipality of Bandung, Indonesia

#### Riantini VIRTRIANA, Iwan KURNIAWAN and Bambang Edhi LEKSONO, Indonesia

Key words: Property, Valuation, NJOP (Government's tax value), Multiple Regression Analysis

#### SUMMARY

Real Property transactions are one of the most important in economic activities. It is also considered that real property system enhancement should be placed as one important agenda to accelerate growth of national economic. Due to rapid economic development activities, it may causes complex real property related activities such us conveyance, mortgage, taxation, and asset valuation. Hence, real property system must have complete, accurate and reliable data bank that used as primary references for valuation and appraisal purposes. In terms of Indonesia, property could assessed by several different institution, such banking, insurance (financial institution), real property agent, and taxation office (government). Those stakeholders asses the same object with different procedure, specification, and point of view as well. Therefore, different value from the same object is common. This research aimed to build up a model of single value of property for multipurpose that based on NJOP (government's tax value) and started with an area of Antapani Kidul Housing, Municipality of Bandung, Indonesia. The modeling of SVMP (Single Value of Property for Multipurpose) are constructed by comparing NJOP with market price data to obtain the differences using statistic method. Hence, difference for every single zone or property classification will then added to NJOP in order to establish the SVMP. This model has six parameters; land price, building price, infrastructure availability, road classification, number of storey within property unit, and the building age. Each parameter is defined to have a different weight. Finally, with statistic computation this model shows a level confident at 95% for each parameter. This SVMP model resulted 102% of difference with existing market price.

## 1. INTRODUCTION

The process of property assessment involves several factors such as information regarding location, land and building width, distance from Center Bussiness District (CBD), structural condition, building construction, etc. Property assessment it self is a very complex procedure. Every individual or government agency involved must have certain parameters as guidance. Unfortunately, in Indonesia there isn't a data bank available for referential use.

The property data bank unavailability causes each property related transaction conducted by society very difficult to be observed, which causes data for evaluation quite minimum, difficult to be accessed and unreliable. It may even causes data manipulation, which results in a non singular assessment of Indonesian property. Assessment will be depend on each agencies ability to gather up much needed information which may vary from one agency to another and cause a different value for one object property.

This research aimed to obtain single value for multipurpose model using NJOP (government's tax value) which able to be used as an approach value towards market value. In the future, this single value model projected as an ideal concept to create single value of property in Indonesia.

#### 2. PROPERTY VALUE

Value according to the American Institute of Real Estate Appraisers is defined as ""the most probable price, as a specified date, in cash, or in term equivalent to cash, or in other precisely revealed terms, for which the specified property rights should sell after reasonable exposure in a competitive market under all conditions requisite to fair sale, with buyer and seller each acting prudently, knowledgeably, and for selfinterest, and assuming that neither is under undue duress".

In accordance with development, the term value doesn't usually stand alone, but used together as a more specific term such us market value, use value, exchange value, insurable value, assessed value, and so on. Market value is defined as an estimated amount of money on a certain date which is obtained from purchase sales transactions or asset tradings between a selling buyer, in a free reasonable transaction, and each party is aware of, cautious and of own willingness (Indonesian Assessment Standards, 2002).

Which also counts for property objects such us land and buildings, those objects are useful and relativity limited in existence. The values of those objects depend on its ability to donate

a use. Land value depends on how and the use of the land it self (Sujarto, 1982). Where structural value, such us a house, maybe approached according with the material satisfaction theory which is based on the thought that a house is based on quantitative and qualitative characteristic components which regards its surroundings and living qualities (O'Sullivan,1996).

## 3. PROPERTY ASSESSMENT AND FACTORS THAT INFLUENCE IT

The principal of property assessment as stated before is an economical concept based on two theories, which are value and approach theory, and assessment techniques respectively. Those theories are applied frequently in property assessment and usually connected with the physical characteristic of the certain property, economical conditions, politics, social and legal aspects which regard rights for the property. Some physical aspects which effect a property value are mainly related with property's width and shape, accessibility, quality of housing and living means, availability of clean water, climate, whether it's a flood free area or not, the view, self comfort, location, and distance from educational, shopping, recreation and other facilities (Sidik,2000).

# 4. PARAMETERS IN PROPERTY ASSESSMENT

In general, some property assessment parameters are:

- Location: topography; land characteristic; usable land area, building borders, land location towards road; view and land outstretch; road access; water availability; distance to town square; and land classification.
- Structural Width: ground floor width, whole width, structural height, ceiling height.
- Construction Quality: material quality.
- Structural Material: material quality, frames, flooring, walls, roof, ceilings.
- Structural Complements: number of rooms, ventilation, drainage facilities.
- Structural Design : architectural style, structural shape.
- Structural Age.

# 5. FORMING A SINGLE VALUE MODEL FOR MULTIPURPOSE USING NJOP DATA AS AN EARLY APPROACH

In the context of property value, there is only one value, which is the market value. Basically the market value reflects the best price for a certain property at the certain time, place and market condition where the property can be sold freely and openly. In other words, basically value is determined by a supply and demand factor in the open market.

## 6. MULTIPLE REGRESSION

In the property market, only few situations show where a dependant variable may be defined quite well by only one independent variable. But in the reality many factors or variable have effect on the value of a dependent variable. Multiple regression is a regression analysis which uses more than one independent variable. Mathematically, multiple regression can be squatted as (Hidayati and Harjanto 2001):

$$Y = b_0 + b_1 x_1 + b_2 x_2 + \dots + b_n x_n + e$$

Where:

| Y       | = Property value, dependent variable  |
|---------|---|
| bo      | = Approximate value   |
| b1,,bn1 | = independent variable co efficiency  |
| x1,,xn  | = independent variable, which can typically be in the form or a round number, |
|         | score, or dummy variable  |
| e       | = error term  |

Hypothesis performed on property value:

- Main Hypothesis on property value
  - In able to select a simple base model for determining an efficient predict value for the property, the main hypothesis has been stated as. It is thought that the ways in assess

```

```

```
TS21.3 A Model of Single Value of Property for Multipurposes (SVMP) Based on Government's Tax Value Approach; Case of Antapani Kidul Housing District, Municipality of Bandung, Indonesia
```

property as a base for determining a single value uses too many variable and results in a less efficient predict value.

- Specific Hypothesis in property assessment For a more specific reason in developing a base model for property value prediction, which is determining key variables that are most relevant in predicting property value, a specific hypothesis has been derived as :
  - Key variables associated with land value
    - Distance to CBD has a negative effect on the property value Land size has a positive effect on the property value Road class has a positive effect on the property value Infrastructure facilities has a positive effect on the property value Proof of land ownership has a positive effect on the property value
  - Key variables associated with structural value
    - Structural size has a positive effect on the property value
    - Number or storey has a positive effect on the property value
    - Effective structural age has a negative effect on the property value
    - Structural condition has a positive effect on the property value
    - Structural construction has a positive effect on the property value
    - Floor, wall, roof and ceiling materials has a positive effect on the property value

| NO | PARAMETERS           | SCORE | FACTORS           |

#### 8. SVMP MODEL 2

Model 1 of SVMP resulted a variation of independent variables which do not effect the independent variables. Model SVMP 2 resulted for every independent variable involved in the hypothesis testing has an effect on its dependent variable and also using a least square method.

Errors that could occur during measurement are related to size, systematic and random error. The purpose of random counting is to find the most appropriate value using random measurement values, which are size and systematic error free. The value most closely to the data can be obtained after all coincidental errors have been eliminated. Weight is given to each measurement in order to obtain a better result. Big score of weight is given to measurement that has a less significance errors (Kahar, 2002).

The multiple regression model used is :

Riantini Virtriana, Iwan Kurniawan, and Bambang Edhi Leksono

TS21.3 A Model of Single Value of Property for Multipurposes (SVMP) Based on Government's Tax Value Approach; Case of Antapani Kidul Housing District, Municipality of Bandung, Indonesia

 $Y = b_o + b_1 x_1 + b_2 x_2 + b_3 x_3 + b_4 x_4 + b_5 x_5 + b_6 x_6 + e$ 

Where:

| = property value, dependent variables |
|---------------------------------------|
| = approximate value                   |
| = independent variable co efficiency  |
| = land size in m2                     |
| = structural size in m2               |
| = road class                          |
| = infrastructural condition score     |
| = number of storey                    |
| = effective structural age            |
| = error term                          |
|                                       |

Co variations used in weight scoring is an exponential function. This exponential function is based on the graphics tendency between measurements and predictions, which shows the result with a smaller standard deviation than using logarithmic and linear functions. A smaller standard deviation shows that the quality of the result is more reliable, in other words, more trust worthy.

TS21 – Valuation and Taxation Riantini Virtriana, Iwan Kurniawan, and Bambang Edhi Leksono TS21.3 A Model of Single Value of Property for Multipurposes (SVMP) Based on Government's Tax Value Approach; Case of Antapani Kidul Housing District, Municipality of Bandung, Indonesia

Figure 1: Observation and prediction value with empiric model

A mathematic model from standard deviation can be seen below :

Where :

V = value added to the result so its original value come closer to reality

n = a number of measurement

u = redundancy

The size of the weight given to each independent variables is  $e^{(-2,3)}$  from the standard residue value of each observation.

 $TS21-Valuation \ and \ Taxation$ 

Riantini Virtriana, Iwan Kurniawan, and Bambang Edhi Leksono

TS21.3 A Model of Single Value of Property for Multipurposes (SVMP) Based on Government's Tax Value Approach; Case of Antapani Kidul Housing District, Municipality of Bandung, Indonesia

Tabel 3: Standard deviation for each function

| Function                    | <b>Standard Deviation</b> |
|-----------------------------|---------------------------|
| <b>Exponential Function</b> | 32,962,498                |
| Logarithmic Function        | 132,091,726               |
| Linear Function             | 43,950,580                |

Results Obtained from SVMP Model 2 are :

- Key Variables associated to land value
  - Land size has a positive effect on the property value
  - Road class has a positive effect on the property value
  - Infrastructure facilities has a positive effect on the property value

- Key variables associated with structural value

- Structural size has a positive effect on the property value
- Number or storey has a positive effect on the property value
- Effective structural age has a negative effect on the property value

## 9. STATISTICAL TESTING FOR SVMP MODEL 2

Summary output results from the SVMP model 2 is as shown below:

| Table 4: Summary Outputs |             |  |  |  |  |  |  |
|--------------------------|-------------|--|--|--|--|--|--|
| Regression<br>Statistics | Value       |  |  |  |  |  |  |
| Multiple R               | 0.999114606 |  |  |  |  |  |  |
| R Square                 | 0.998229996 |  |  |  |  |  |  |
| Adjusted R<br>Square     | 0.997970972 |  |  |  |  |  |  |
| Standard Error           | 3989462.471 |  |  |  |  |  |  |
| Observations             | 48          |  |  |  |  |  |  |

From the multiple regression analysis results shown above, we can see that the value of *r*-squared is 0,998229996 or 99,80 % which means that 99,80 % of independent variable variations explain their independent variable variations, it also means that only 0,20 % of independent variable variations are determined by the other variables included in the error term. According to multiple regression analysis results, adjust *r*-squared value is 0,997970972.

Statistical testing for each independent variable with a reality value of 5%, each independent variable co efficiency refuse zero hypothesis = 0 if significant F value is smaller than 0,05. Significant F value obtained is 9,238833 E-55 which means that zero hypothesis is refused entirely from that model. Significant F value may be seen in the following diagram.

TS21 – Valuation and Taxation

Riantini Virtriana, Iwan Kurniawan, and Bambang Edhi Leksono

| Number of<br>storey   | 9661080.05   | 4958088.313       | 1.948549408  | 0.05821546  |
| Building Age          | -2283351.62  | 337763.9733       | -6.760198831 | 3.59707E-08 |

Regression analysis results from the SVMP model 2 show that independent variables from land size, structural size, infrastructural facilities, and structural age have a large effect toward the dependent variables value or market price.

Information Obtained From Regression Analysis Using The SVMP Model 2

- If the land size increase one square meter, than the property value would increase 657 thousand rupiahs.
- If the structural size increase one square meter, than the property value would increase 835 thousand rupiahs.
- If the road class quality increase by one level, than the property value would increase 14,5 million rupiahs.
- If the infrastructural facilities increase, than the property value would increase 32 million rupiahs.
- If the number of storey increase one level, than the property value would increase 9,6 million rupiahs.
- The older property gets, each year its value decreases 2,2 million rupiahs.

TS21.3 A Model of Single Value of Property for Multipurposes (SVMP) Based on Government's Tax Value Approach; Case of Antapani Kidul Housing District, Municipality of Bandung, Indonesia

The transaction price accumulated according to the parameters that have been set become a single value which can be used as a reference in doing assessment, so obtaining a single value using NJOP data as an approach can be seen in the mathematical formula below :

#### $\mathbf{SVMP} = \mathbf{NJOP} + \Delta$

With  $\Delta$  as the difference between the single value obtained from the SVMP model 2 with NJOP.  $\Delta$  value will be added to NJOP so an adequate market value can be obtained and set as a single value for multi purposes. Ref. appendix 1.

#### **10. CONCLUSION**

After going through several processes during the study, some conclusions which refer to the point and target of this study are:

- NJOP may be considered as an early approach in determining a single value for multipurpose related to housing type property assessment.
- Single value is representation of a property's rational standard market value, which enable an adequate property market value.
- Model of SVMP with weighting function is the best model for the study case area. According to statistical testing this model shows that parameters used are very reliable (p-value < 0.05) which are able to represent actual condition. The six parameters used are land width, structural width, infrastructural facilities, structural age, number of storey, and road class.
- The Antapani Kidul housing district is an area with homogeny component, so structural component parameters (floor type, wall type, roof, ceilings, structural construction and condition) statistically have no significant effect on property assessment in that region.
- Parameters used in forming a single value model may vary from one area to another.

#### RECOMMENDATION

- For upcoming research, a larger administration area should be studied, starting from a sub district, city, up to a provincial level, so a more representable single value model for Indonesia may be obtained
- To obtain single value with a close to zero residues, another research to create a new model besides the regression model used in property assessment process should be conducted.
